**The Production of Synthetic Rutile and By-Product Iron
Oxide Pigments from Ilmenite Processing**

Abstract

A study has been carried out on the Becher and Summit Processes with the aim of understanding the mechanism and critical parameters required for the production of a range of pure iron oxide pigments, as well as high quality synthetic rutile from reduced ilmenite.

The Becher Process currently produces a large quantity of worthless mixed phase iron oxides. However, this study has shown that the range of iron oxides formed are all derived from the transformation of lepidocrocite ($\gamma\text{-FeOOH}$) through the solution phase in iron(II) solutions. The results of a kinetic study of the transformation of lepidocrocite found that the rate exhibited an induction period at low pH, was dependent on temperature and was linearly related to $\log [\text{H}^+]$ and $\log [\text{Fe}^{2+}]$. The rate determining step was found to be the formation of suitable product nuclei, following dissolution of the initial oxide at the surface of the crystal lattice.

An electrochemical study of these reactions showed that the product formed from the transformation of lepidocrocite was a function of the solution potential and an experimental Eh-pH diagram was constructed to predict the iron oxide phase produced from hydrolysis and transformation reactions. The results from this fundamental study were then applied on both a laboratory and plant scale to produce pure iron oxide phases.

A modified Summit Process, involving the removal of metallic iron from the porous reduced ilmenite matrix using FeCl_3 , regeneration of iron(III) and the production of pure iron oxide pigments from the waste iron(II) chloride solution, was also investigated in detail.

A kinetic study of pure iron dissolution in iron(III) solutions, comparing three electrochemical techniques and a standard solution sampling method, gave consistent rate constants provided allowance was made for the reaction with the proton. The iron dissolution mechanism was found to be iron(III) diffusion controlled, while the dissolution in HCl was under mixed control. A study using both pure iron and pressed reduced ilmenite discs found that acid consumption could be minimised by the addition of citrate or by the addition of Al^{3+} or Fe^{2+} , which are believed to block the adsorption of the proton. It was found that iron(III)-citrate complexes inhibited iron(III) hydrolysis in the reduced ilmenite pores and enhanced the purity of the synthetic rutile product.

A study of the oxidation of iron(II) by atmospheric oxygen using copper(II) and activated carbon catalysts found that these catalysts were inefficient for complete iron(III) regeneration. The heating of carbon in the presence of Cu^{2+} was found to enhance the initial rate of iron(II) oxidation, however it is believed that surface oxide redox couples formed on the carbon control the iron(II)/iron(III) ratio in solution, and prevent complete iron(II) oxidation. The production of iron oxide pigments under the controlled conditions afforded by the Summit Process, resulted in superior quality pigments than are presently attainable from the Becher Process. However, controlled ageing and crystal growth using waste lepidocrocite from the Becher Process would result in similar quality pigments being produced.

I declare that this thesis is my own account of my research and contains work which has not previously been submitted for a degree at any University.

Acknowledgements

I wish to sincerely thank my supervisors Associate Professor David Muir (principal) and Professor Ian Ritchie for the interest, help and guidance afforded me during the course of this work, which helped make the life and work at Murdoch University a most rewarding experience.

Acknowledgement must also be made to a number of the staff at Westralian Sands Ltd, Capel, in particular Mr. C. Pearson, Mr. N. Bernard and Mr. C. Ryan, who helped in supplying samples and for the valued discussions held throughout this project. Financial support supplied by the company for this project and to employ Mr G. Patrick and Miss S. Gibbons, to develop some of the commercial aspects leading from this work was appreciated. The efforts of these Research Assistants is also acknowledged for their assistance during the plant trials conducted on site at the Westralian Sands Synthetic Rutile Plant.

The assistance of the technical staff of both the Mineral Science and Chemistry programmes of the School of Mathematical and Physical Sciences is gratefully acknowledged, in particular Mr. J. Biddle and Mr. T. Osborne. Their help and technical know-how was invaluable and without them this project would not have progressed as smoothly.

Last but not least, I wish to thank my wife, Anne, for her continual support and encouragement throughout.

CHAPTER 1. The Production of Synthetic Rutile and By-Product Iron Oxide Pigments from Ilmenite Processing.	1
1.1 Introduction	1
1.2 The Need for Ilmenite Upgrading	3
1.2.1 The "Sulfate" Process	4
1.2.2 The "Chloride" Process	5
1.3 By-Products from the Upgrading of Ilmenite	6
1.3.1 The Becher Process	9
1.3.2 The Summit Process	13
1.4 Scope of this Thesis	15
1.5 Purpose of this Study	17
CHAPTER 2. Methods of Production and Transformation of Iron Oxides.	19
2.1 Introduction	19
2.2 Hydrolysis of Iron	19
2.3 Iron Oxide Transformation Reactions	24
2.3.1 Thermal Interconversions	26
2.3.2 Mechanical Interconversions	27
2.3.3 Aqueous Interconversions	28
2.4 Results and Discussion	31
2.4.1 Identification and Production of Iron Oxides from the Becher Process	31
2.4.2 Iron Oxides from Laboratory Scale Aerations	33

2.4.3	Transformation of Aerator Test Products	34
2.4.4	Transformation of ^{59}Fe Isotope Doped Lepidocrocite	39
2.4.5	Effect of Metallic Iron and Other Reductants on the Transformation Products	40
2.5	SEM Analysis of the Iron Oxides from Aerator Tests	43
2.5.1	Initial Products	43
2.5.2	Transformed Products	47
2.6	Experimental	55
2.6.1	Identification and Production of Aerator Iron Oxides	55
2.6.2	Transformation Experiments	55
2.6.3	X-Ray Diffraction Analysis	56
2.6.4	Scanning Electron Microscope Analysis	57
2.6.5	Transformation of ^{59}Fe Isotope Doped Lepidocrocite	57
2.7	Conclusions	58
CHAPTER 3.	Kinetics and Mechanism of Lepidocrocite Transformations	60
3.1	Introduction	60
3.2	Experimental	61
3.2.1	X-Ray Diffraction Analysis	61
3.2.2	Thermogravimetric Analysis	62
3.3	Results	62
3.3.1	Lepidocrocite Transformation Kinetics	62
3.3.2	Effect of pH	66
3.3.3	Effect of Seeding on the Rate and Product Distribution of the Transformation Reaction	70
3.3.4	Effect of Temperature	74
3.4	Discussion	76
CHAPTER 4.	Electrochemistry and Thermodynamics of Iron Oxide Transformation Reactions	81
4.1	Introduction	81

4.1.1	Electrochemistry of Iron Oxide Phases	81
4.1.2	Experimental Programme	83
4.2	Experimental	84
4.2.1	Polarization of Pressed Iron Oxide/Carbon Electrodes	84
4.2.2	Calorimetry	87
4.2.3	Carbon Paste Electrodes	88
4.2.4	Mixed Potential of Reduced Ilmenite Samples	88
4.3	Results and Discussion	89
