Abstract

Use of bauxite refining residue to reduce the mobility of heavy metals in municipal waste compost.

PhD thesis by

Harrie Hofstede

Due to the adverse environmental impact of landfills and the lack of space for nearby population centres an unprecedented interest has developed in waste recycling with the objective to reduce the volume of waste disposed. Generally organic matter represents the largest fraction in the domestic waste stream including food, garden and paper waste.

In the past efforts have been made to process this organic fraction into municipal compost. However contamination of the compost with heavy metals has in many cases resulted in the lack of suitable markets and subsequent closure of compost facilities. A study was undertaken and aimed at reducing the concentration and mobility of heavy metals in municipal compost.

Bauxite refining residue has a high capacity to immobilise metals in soils through precipitation, cation exchange and chemisorption (Fe- and Al- oxides).

The first step in the study was to assess the metal adsorption capacity of red mud by equilibrating red mud with metal solutions. Metal removal from solution proved very high.

Subsequently, the effect of red mud addition to municipal compost was studied in relation to metal mobility. In particular the interaction of metals with the mobile soluble organic fraction, the humic and fulvic acids, was investigated. It was found that most metals remained in the insoluble humin fraction and the metals in solution remained complexed to the soluble organic fraction. Red mud appeared to be able to adsorb fulvic and humic acids and thus indirectly immobilise the metals in solution. Red mud did not appear to be able to transfer metals from the organic fraction to the mineral red mud fraction.

It was hypothesised that, in order for the metals to be adsorbed to red mud, the red mud needed to be present in the organic waste prior to composting. Metal adsorption to red mud is a rapid chemical reaction while metal complexation to the organic fraction takes a number of weeks, since it must be sufficiently oxidised to contain functional groups

In order to verify this hypothesis, an installation with seven incubators was developed which allowed composting to be undertaken under computer controlled conditions and monitored for temperature, airflow and carbon dioxide respiration. The incubators were filled with 10 kg of a mixture of grass clippings and sawdust. The first incubator functioned as a control. The contents of the rest of the incubators were spiked with the following metals: Cd, Cr, Cu, Ni, Pb and Zn. In addition the contents of the 3rd - 7th incubators were amended with an increasing percentage of red mud, respectively 10, 20, 25, 30 and 40 % by weight. After the mixture was composted, the metal mobility was reduced by approx. 80 - 99 %, depending on the metal. The mobility was assessed as leachable and plant available in relation to the total metal content. Red mud did not affect the composting process if < 40 % red mud was added.

The next step was to compost municipal organic waste in a pilot plant (capacity 5 m³) using batches with and without red mud. Mixed waste was collected from 150 households and the glass, metal and plastic fractions were removed by manual sorting. The rest was composted.

The red mud - compost had a relatively lower metal content and a reduced metal mobility compared to compost without red mud. The red mud - compost also had a 300 times higher pH buffer capacity and 90 % less soluble organic matter.

The addition of red mud prior to composting was found to reduce the concentration and mobility of metals in compost, improve the quality of compost as a soil conditioner, increased the resistance of the organic fraction against further breakdown and this process thus adds value to both red mud and organic waste.

Acknowledgement

I would like to acknowledge the assistance and support of the following persons, who in many different ways provided assistance and support in carrying out this research effort.

- Associate Professor Goen E. Ho for supervision and intellectual stimulation.

- Ms Hillary Capolingua for personal support and regular distractions.

- Mr Don Glenister, Alcoa of Australia, for taking an interest in the research and provision of financial support.

- Mr Stephan Frodsham, Department of Commerce and Trade, WA Government for support and financial assistance.

- Mr Wally Piscetek, City of Perth, for his enthusiasm and provision of engineering and financial support.

- Technical staff at Environmental Science for construction of equipment and challenging technical discussions.

- Ms Marcia Hawdon, who is now an expert in deciphering and digitising my handwriting.

6.34	The oxygen and carbon dioxide concentrations in the effluent gas and the temperature during composting with 40% red mud	177
6.35	Solubilisation of organic matter during the thermophilic stage of composting measured as the chemical oxygen demand of a water extract	178
6.36	The mass balance of the composting process in the control incubator	187
6.37	The mass balance of the composting process in the blank incubator	188
6.38	The mass balance of the composting process in the incubator with 10% red mud amendment	188
6.39	The mass balance of the composting process in the incubator with 20% red mud amendment	189

6.40	The mass balance of the composting process in the incubator with 25% red mud amendment	189
6.41	The mass balance of the composting process in the incubator with 30% red mud amendment	190
6.42	The mass balance of the composting process in the incubator with 40% red mud amendment	190
7.1	Diagram of the composting pilot plant	203
7.2	Temperature, moisture content, organic matter content, pH and soluble organic matter during composting (run 1)	217
7.3	Temperature, moisture content, organic matter content, pH and soluble organic matter during composting (run 2)	221
7.4	Temperature, moisture content, organic matter content, pH and soluble organic matter during composting (run 3)	226

List of tables

No.	Title	Page
1.1	Current and future heavy metal standards in municipal compost	3
1.2	Heavy metals in municipal solid wastes	4
2.1	Number of functional groups per molecule of soil humic acids and soil fulvic acids	25
2.2	Sequence of affinity of divalent metal ions for soil organic matter related to selected properties of metals	27
2.3	Particle size distribution of bauxite refining residue	40
2.4	Negative logarithm of the solubility product of metal precipitates (pK_s)	43
3.1	Settling velocity of red mud at different initial heavy metal concentrations	60
3.2	Metals for which experimental adsorption isotherms could be determined	80
3.3	The correlation coefficients between the isotherms of red mud gypsum (RMG) and red mud acid (RMA) and the Langmuir and Freundlich equations for both single metal and preferential adsorption	80
3.4	Maximum metal adsorption capacity for RMG and RMA for individual and mixed metal solutions according to the Langmuir equation	82
4.1	Results of Auckland municipal compost analysis	95
4.2	Effect of red mud on the exchangeable and acid extractable zinc and lead (mg/kg compost) in municipal compost.	96
4.3	The effect of red mud on plant available and soil solution soluble cadmium, copper and nickel concentrations	98
4.4	UV absorbance at four wavelengths and the E_4/E_6 ratios and $\Delta \log K$ values of fulvic and humic acids in compost	99
4.5	K_{av} values of fulvic acids obtained from compost/red mud mixtures separated on a Sephadex G-10 column	100
4.6	The distribution of copper and zinc in the soluble organic fraction of compost	103
4.7	Total organic carbon concentrations in compost extracts with red mud and the effect of humic acid removal	106
4.8	The effect of red mud on the $\Delta \log K$ and E_4/E_6 values of compost extracts	111

4.9	The effect of increasing red mud and red mud-gypsum additions to compost and to water extracts of compost on the absorbance of the extracts at their most sensitive wavelength	112
4.10	Effect of gypsum amendment of red mud on metal leaching from a red mud - compost percolation column	115
5.1	Compost process and maturity parameters and the analytical methods applied	127
5.2	Statistical analysis of the sum of the carbon dioxide and oxygen balance during the composting process	131
5.3	Total organic carbon, total nitrogen and the C/N ratio during composting	133
5.4	The carbon and nitrogen balance at three time intervals	134
5.5	The mass balance during composting	136
6.1	Substrate consistency of the batches in each compost reactor	143
6.2	Metal concentrations in the spiking solution and compost	143
6.3	Relevant parameters and frequency of monitoring or analysis	146
6.4	Test of the significance of the effect of red mud addition on the leachable and plant available heavy metals using analysis of variance	149
6.5	The reduction in metal mobility for each metal as a function of red mud addition and as a function of time	162
6.6	Heavy metal content of red mud and the metal recovery from red mud with acid after equilibration with the spiking solution	168
6.7	Effect of red mud on the relative metal mobility indexed to the blank	169
6.8	Statistical analysis of sum of the oxygen and carbon dioxide concentration	171
6.9	The E ₄ /E ₆ ratio in the separate fulvic and humic acid fractions during composting	180
6.10	Effect of red mud on the pH buffer capacity of the final compost and the relation to loss of carbon as CO ₂	181
6.11	The correlation between the loss of carbon during composting and red mud addition as well as the buffer capacity	182
6.12	The effect of red mud on the carbon to nitrogen ratio in the substrate during the thermophilic stage of composting	183
6.13	Electrical conductivity in compost - red mud extracts	184

6.14	Macro elements and total nitrogen content of the blank and the 20% red mud amended compost	185
6.15	The pH levels required to be exceeded before metal hydroxide precipitation takes place	194
7.1	Composition of the domestic waste	213
7.2	The total organic carbon, total nitrogen and the C/N ratio of the waste during composting	216
7.3	Total metal content in municipal red mud-compost and the plant available and leachable fractions (run 1)	218
7.4	Compost particle size distribution on the basis of weight (run 1)	219
7.5	The carbon to nitrogen ratio in plain municipal waste during composting	222
7.6	Heavy metal content in mature plain municipal compost and the plant available and leachable fractions (run 2)	224
7.7	The particle size distribution in plain municipal compost (run 2)	224
7.8	Development of the C/N ratio during red mud amended municipal waste composting (run 3)	227
7.9	Heavy metal content in mature municipal red mud-compost and the plant available and leachable fractions (run 3)	229
7.10	Compost particle size distribution (run 3)	230
7.11	A comparison of the mass balances for each run	230
7.12	The leachable and plant available heavy metals as a percentage of the total metal concentration in the compost	235

List of Plates

No.	Title	Page
7.1	Pilot plant setup with conveyor belt, reactor, motor and gear box and the sorting bins	204
7.2	Mixed domestic waste on the conveyor belt prior to sorting and discharge of organic fraction into the reactor	205
7.3	The red mud compost of run I after discharge from the reactor and prior to maturation	237
7.4	The plain municipal compost of run 2 after discharge from the reactor and prior to maturation	237
